Details about the discovered false alarms

With AV testing it is important to measure not only detection capabilities but also reliability - one of reliability aspects is certainly product's tendency to flag clean files as infected. No product is immune from false positives (FP's) but there are differences among them and the goal is to measure them. Nobody has all legitimate files that exist and so no "ultimate" test of FP's can be done. What can be done and is reasonable, is to create and use a set of clean files which is independent. If on such set one product has e.g. 50 FP's and another only 10, it is likely that the first product is more prone to FP's than the other. It doesn't mean the product with 10 FP's doesn't have more than 10 FP's globally, but important is the relative number.

All listed false alarms were reported and sent to the Anti-Virus vendors for verification and should now be already fixed. False alarms caused by unencrypted data blocks in Anti-Virus related files were not counted. If a product had several false alarms belonging to the same software, it is counted here as only one false alarm. Cracks, keygens, etc. or other highly questionable tools, including FP's distributed primary by vendors (which may be in the several thousands) or other non independent sources are not counted here as False Positives.

In order to give more information to the users about the false alarms, we try to rate the prevalence of the false alarms. Files with valid digital signatures are considered more important. Due to that, a file with e.g. prevalence "level 1" and a valid digital signature gets upgraded to next level (e.g. prevalence "level 2").

The prevalence is given in 5 categories and labeled with the following colors: 

Level		Presumed number of affected users	Comments
1		Probably fewer than hundred users	Individual cases, old or rarely used files, unknown prevalence
2		Probably several hundreds of users	Initial distribution of such files was probably higher, but current usage on actual systems is lower (despite its presence), that's why also well-known software may now affect / have only a prevalence of some hundreds or thousands of users.
3		Probably several thousands of users	
4		Probably several tens of thousands (or more) of users	
5		Probably several hundred of thousands (or millions) of users	Such cases are likely to be seen very less frequently in a false alarm test done at a specific time, as such files are usually either whitelisted or would be noticied and fixed very fast.

Most false alarms will probably most of the times fall into the first two levels. In our opinion Anti-Virus products should not have false alarms on any sort of clean files despite how many users are affected by them. While some AV vendors may play down the risk of false alarms and play up the risk of malware, we are not going to rate products based on what the supposed prevalence of false alarms is. Currently we already allow a certain amount (15) of false alarms inside our clean set before we start penalizing scores and in our opinion products which produce a higher amount of false alarms are also more likely to produce false alarms on more prevalent files (or in other sets of clean files). The prevalence data we give about clean files is just for informational purpose. The listed prevalence can differ inside the report depending on which file / version the false alarm occurred and/or how many files of same kind were affected.

Some products using third-party engines/signatures may have fewer or more false alarms than the licensed engine has by its own, e.g. due to different internal settings implemented, the additional checks/engines/clouds/signatures, whitelist databases, time delay between the release of the original signatures and the availability of the signatures for third-party products, additional QA of signatures before release, etc.

False Positives (FPs) are an important measurement for AV quality. One FP report from a customer can result in large amount of engineering and support work to resolve the issue. Sometimes this can even lead to important data loss or system unavailability. Even "not significant" FPs (or FP's on old applications) deserve mention and attention because FPs are likely to be a result of principled rule detections. It just happened that the FP was on an insignificant file. The FP possibility is probably still in the product and could FP again on a more significant file. Thus, they still deserve mention and still deserve penalty.

Below you will find the false alarms we observed in our independent set of clean files. Red entries highlight false alarms on files with valid digital signatures.

Microsoft

Microsoft had zero false alarms over our set of clean files.

ESET
